DATABASE FUNDAMENTALS

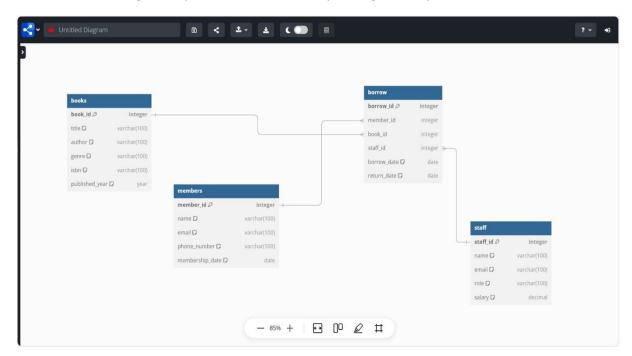

Database Fundamentals

- **Definition**: A database is an organized collection of data that can be easily accessed, managed, and updated. Databases are essential for storing large volumes of data in an efficient and structured manner.
- Types of Databases:
 - Relational (RDBMS) NoSQL (e.g.,
 - MongoDB)
 - Hierarchical
 - Object-oriented
- **Database Management System (DBMS)**: Software that manages databases. Examples include MySQL, PostgreSQL, Oracle DB, and MongoDB.

Database Concepts and Architecture

- Three-Tier Architecture:
 - o Physical Layer: Storage of data on disks.
 - Logical Layer: Defines the structure of data (schemas, tables, relationships).
 - o View Layer: How users interact with data (via queries or UI).
- · Schemas:
- O Physical Schema: Defines physical storage.
- o Logical Schema: Defines the structure (tables, views).
 - View Schema: Subset of data accessible to users.
- **Client-Server Architecture**: Databases operate in a client-server model where a server hosts the database, and clients access it.

Practical Task: Design a simple schema for a "Library Management System. book store"

Relational Database Management Systems (RDBMS)

- **Definition**: A type of database that organizes data into tables (rows and columns) and uses relationships to connect them.
- Key Features:
 - Structured Data
 Data Integrity
 Use
 of SQL for operations
- Examples: MySQL, PostgreSQL, Oracle, Microsoft SQL Server.

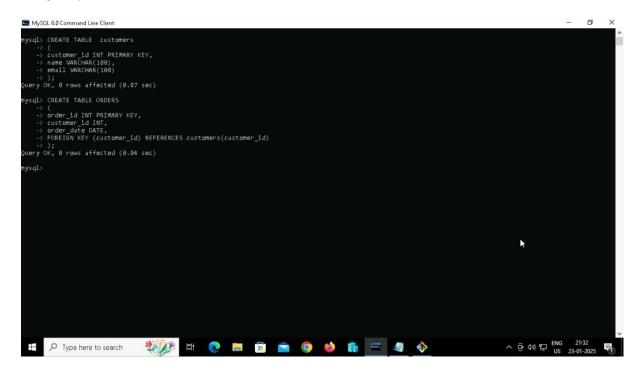

Practical Task:

Create a table called books with columns: id, title, author, published_year, and genre.

Tables and Relationships

- Table: A collection of rows (records) and columns (fields). Each table represents an entity.
- Relationships:
 - o **One-to-One**: Each row in Table A maps to one row in Table B.
 - o **One-to-Many**: One row in Table A maps to multiple rows in Table B.
 - Many-to-Many: Multiple rows in Table A map to multiple rows in Table B via a junction table.

Create two tables: customers and orders. Define a one-to-many relationship between them using foreign keys.

Primary Keys and Foreign Keys

- Primary Key:
 - Uniquely identifies each row in a table.
- Cannot contain NULL values.

- Example: id in a users table.
- Foreign Key:
 - o Establishes a relationship between two tables.
 - Refers to the primary key in another table. o table references id in the users table.

Example: user_id in an orders

Create a table departments with a primary key, and another table employees with a foreign key referencing departments.

SQL Basics

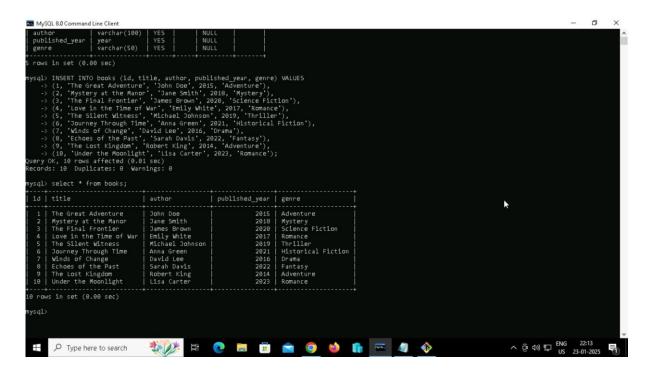

- **SELECT**: Retrieve data from a table.
- INSERT: Add new data to a table.
- **UPDATE**: Modify existing data.
- **DELETE**: Remove data.

Practical Task:

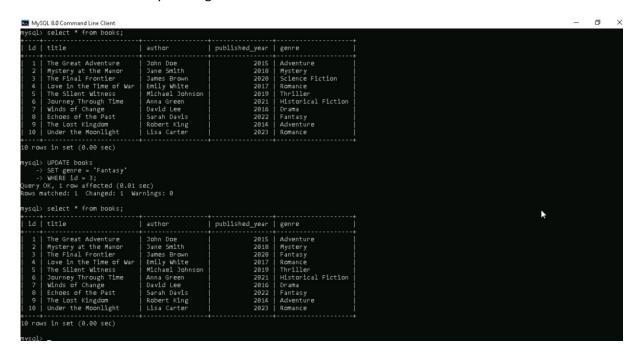

Perform CRUD operations on the books table

Inserting Data into books table

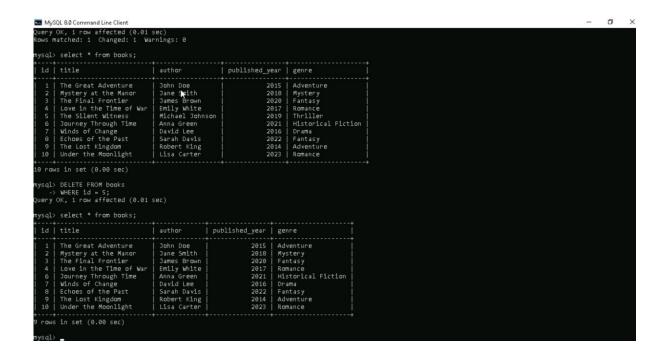

SELECT Retrieve data from a table.

UPDATE: Modify existing data.

DELETE: Remove data.

Normalization

- **Definition**: Process of organizing data to reduce redundancy and improve efficiency.
- Forms of Normalization:
 - o **1NF (First Normal Form)**: Ensure atomic values and unique rows.
 - o **2NF (Second Normal Form)**: Eliminate partial dependencies.
 - 3NF (Third Normal Form): Remove transitive dependencies.
 - o **BCNF (Boyce-Codd Normal Form)**: Handle more complex dependencies.

Transactions and ACID Properties

- Transaction: A sequence of database operations treated as a single logical unit.
- ACID Properties:
 - Atomicity: Transactions are all-or-nothing.
 - o **Consistency**: Transactions bring the database from one valid state to another.
 - Isolation: Transactions do not interfere with each other.
 - Durability: Once committed, data remains saved even in case of a failure.

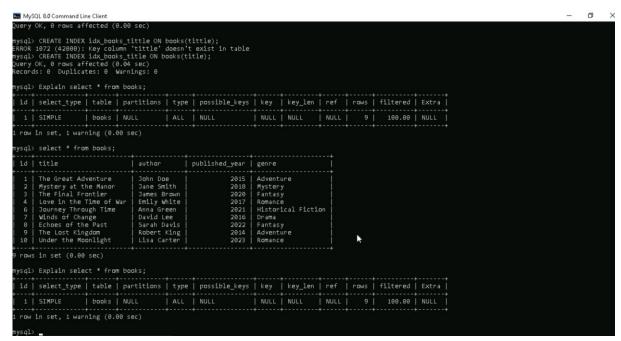

Perform a transaction with multiple SQL operations and test rollback.

Indexes

- **Definition**: A database optimization technique to speed up data retrieval.
- Types:
 - o **Primary Index**: Automatically created for the primary key.
 - Secondary Index: Manually created on other columns for faster lookups.
- Trade-offs:
 - o Improves SELECT queries.
 - o Slows down INSERT/UPDATE/DELETE due to index maintenance.

Create an index on the title column of the books table.

Database Design

- Steps:
 - o **Requirement Analysis**: Understand data needs.
 - Conceptual Design: Create Entity-Relationship (ER) diagrams.
 Logical Design: Define tables, relationships, and keys.
 - o **Physical Design**: Optimize storage and indexing.
- Best Practices:
 - o Use normalization. o Avoid redundancy. o Optimize queries for performance.

Practical Task:

- Design a database for an "Online Store" using:
 - o Entities: Products, Categories, Orders, Customers.
 - o Relationships: Define primary keys and foreign keys.

Backup and Recovery

- Backup:
 - Regularly save copies of database data.
 - Types: Full, Incremental, Differential.
- - o **Point-in-Time Recovery**: Restore database to a specific moment.
- Tools:
 - o MySQL Backup Tools, pg_dump (PostgreSQL), RMAN (Oracle).

Practical Task:

- Perform a full backup of your database:
 mysqldump -u root -p my_database > my_database_backup.sql
- Simulate a data loss scenario by dropping a table, then restore it:
 DROP TABLE books;
 - -- Restore using the backup
 SOURCE my_database_backup.sql;
